

# Fast Response Engine Research

Ryan May

ASRC Aerospace Corp

2012 PCD Workshop

Cleveland, Ohio

# Overview

- Why do we want faster engine response?
- Challenge
- Approaches
  - Controller Gain Modification
  - Risk-Based Limit Modifications
  - High Speed Idle
- Conclusions

# The Case for Faster Engine Response

- Use of engines can increase the likelihood of recovering the aircraft
- From Dryden studies after UA232: engines are too slow

# Challenges

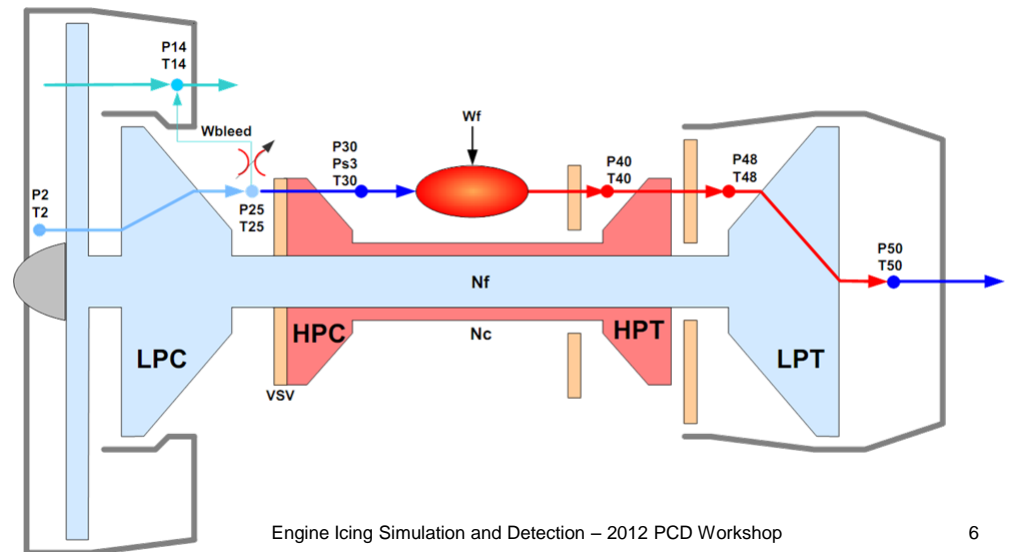

- Engine behavior is highly non-linear with different response based on:
  - Initial power setting and final power setting
  - Operating condition (altitude, Mach, ambient temp)
  - Engine age
- Regulatory/certification challenges
- Using the engine in an “atypical” manner presents risk of engine failure (either immediate or gradual)

# GRC Approaches to Faster Response

- Requirements: Must not change the basic architecture of the existing control system
- Use a number of approaches to improve response
  - Increase controller gain – small throttle changes
  - Relax engine limits – large throttle changes, edge of envelope operation
  - Change engine operating point using actuators off-nominally
- C-MAPSS40k used as development platform

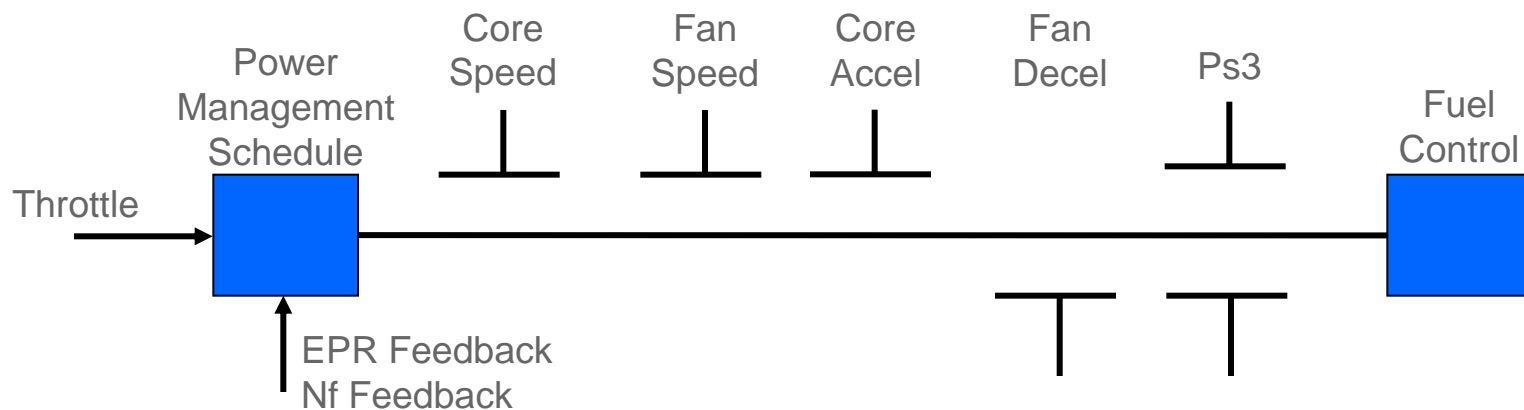

# C-MAPSS40k

- C-MAPSS40k engine simulation
  - Commercial 40,000lbf thrust, high-bypass turbofan engine
  - Physics-based model
  - Realistic engine control system
  - Written in MATLAB/Simulink
  - Modular design

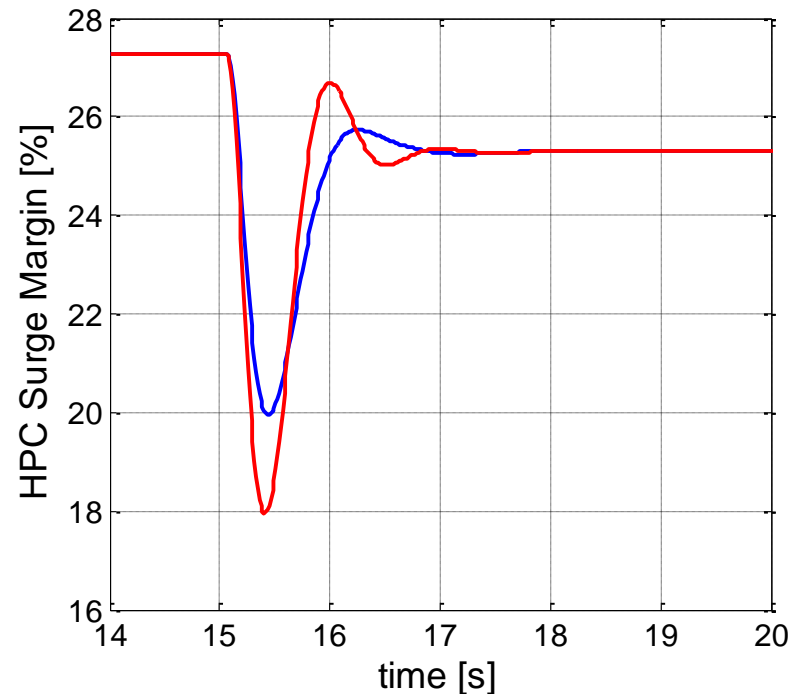

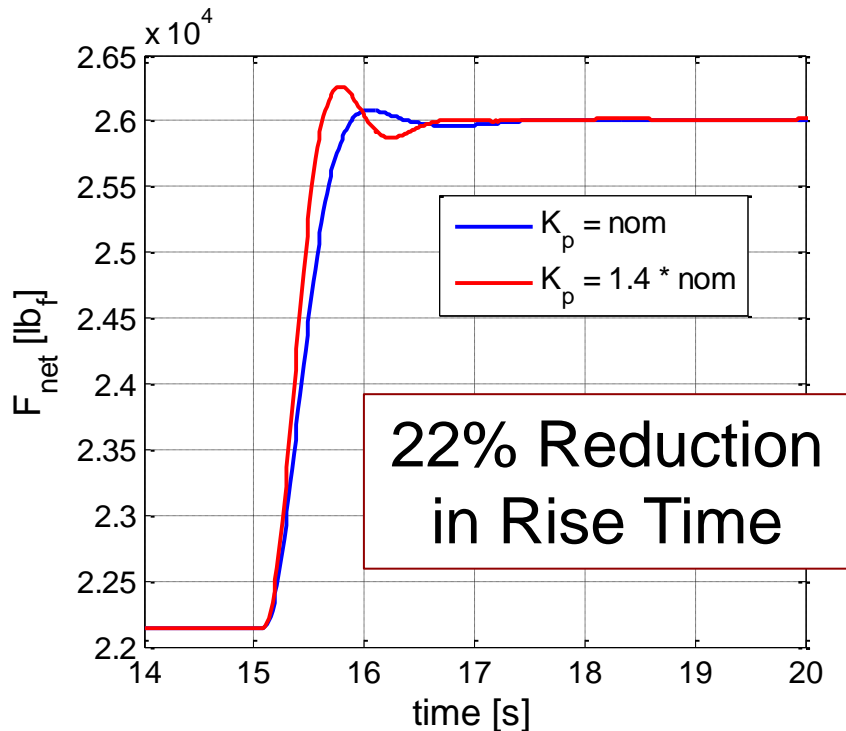

# Engine Control System

- Power Management
  - Responsible for holding current power level (EPR or Nf)
- Protection Logic
  - Responsible for ensuring safe operation
  - Adjusts Fuel Flow to ensure limits are observed

# Controller Gain Modification

- Changing the setpoint controller's gain will improve response during small transients
- Increase in gain reduces stability margins
- Marginal impact on HPC Surge Margin

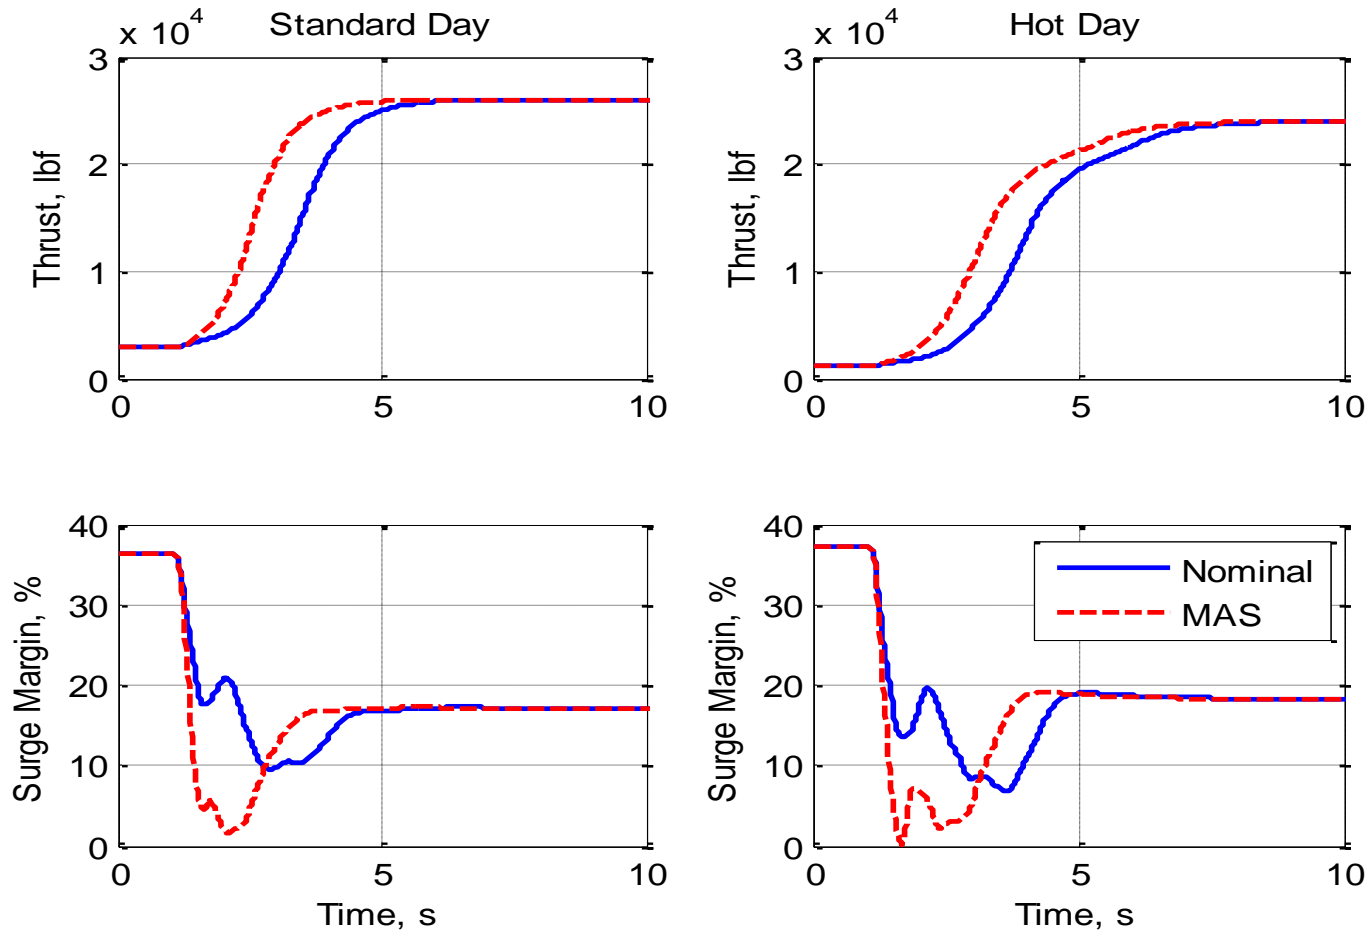

# Risk-Based Limit Modification

- Primary concern during large throttle transients is compressor surge margin
- Can “relax” the acceleration limit
  - Improved response and decrease in surge margin
- Is it worth it?
  - New engines have “extra” SM
  - SM changes based on environment
- Can minimize the risk with increased knowledge of current state, but any change will increase risk of surge
  - Must choose an acceptable risk that balances chance of engine failure with aircraft survivability

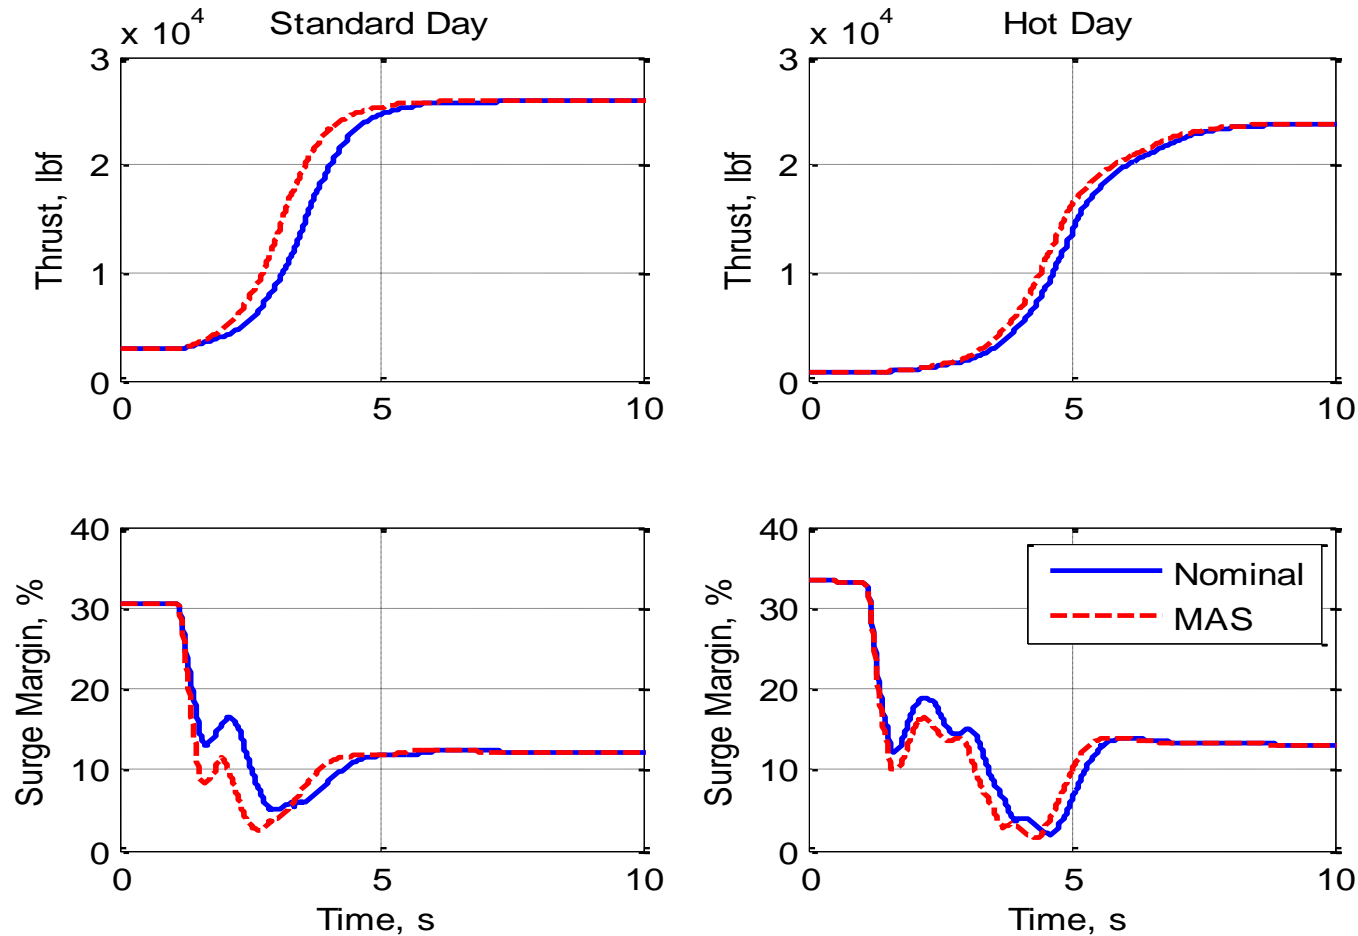

# Risk-Based Limit Modification

- Response of a new engine to full throttle change

# Risk-Based Limit Modification

- Response of an old engine to full throttle change

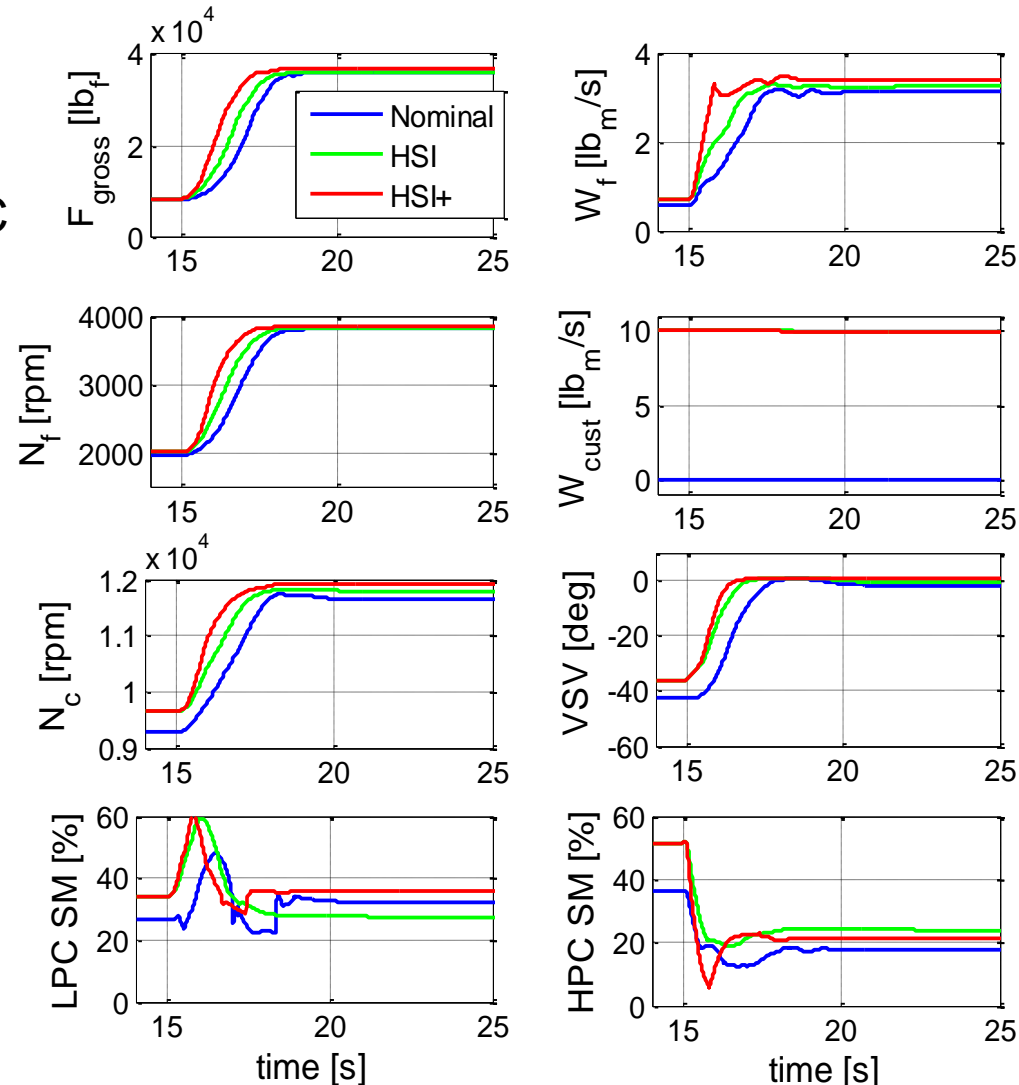

# High Speed Idle

- Designed to improve engine response during approach
- To safely increase engine acceleration we must operate in a region where HPC surge is not as much of a concern
  - Operate at higher shaft speeds
  - Reduces the potential fan/core mismatch
  - Higher speeds lead to more thrust
- During approach/landing it is critical to balance the aircraft's energy
- Engine can be operated in an off-schedule manner to reduce excess thrust
  - Move compressor vanes off-nominal
  - Bleed air from engine components
  - Extract power from shafts
  - etc

# High Speed Idle

- Increase engine idle setpoint
- Reduce excess thrust
  - Move VSV  $-5^\circ$  (serves to shift HPC speed lines to the left)
  - Bleed air from core to airframe using customer bleed
  - Close VBV
- Can relax accel limit due to higher steady-state HPC SM (HSI+)
- Increase in thrust (3.7%)
- Increase in fuel consumption (24.2%)

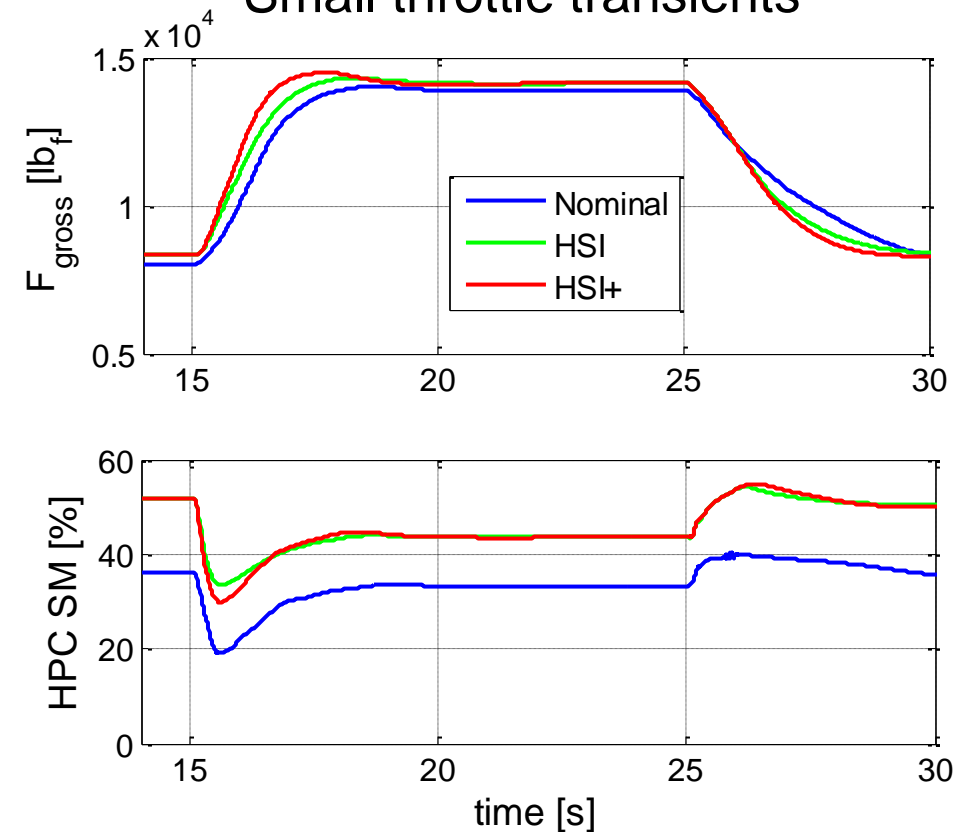

Control Law	Time Constant
Nominal	2.28 s
HSI	1.81 s
HSI+	1.36 s

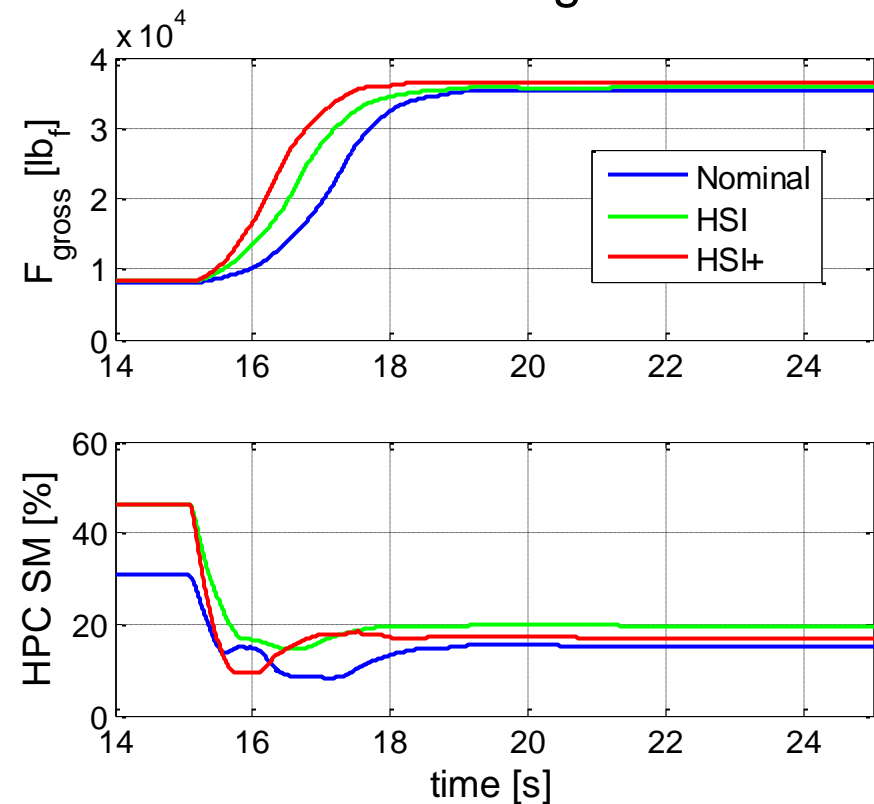

# High Speed Idle

- Same trends and response improvement observed for:

## Small throttle transients

## End-of-life engines

# Conclusions

- It is possible to improve response of C-MAPSS40k with only changes to gains and limits, and by using existing actuators in novel ways.
- Any change will increase the risk of engine failure
- May be acceptable in emergencies if improvement in performance results in increased survivability of aircraft
